ATTY-AGENT-FIRM: Graham; David R.

ABSTRACT:

The invention enables multiple users to simultaneously access and change the contents of a database in a flexible manner. Each user interacts with a working copy of a master copy of the database. The contents of each of the working copies of the database can be accessed and manipulated so that the contents of the working copy of the database can be revised. Each user has control over whether to the "publish" revisions made to the contents of that user's working copy of the database, i.e., write the revisions to the master copy and present other users with the option of including the revisions in the working copies of those other users. Each user has the option to reject revisions published by other users so that the contents of each user's working copy of the database may or may not be maintained consistent with other working copies of the database operated on by other users. However, in order to ensure data integrity of the master database, each user that rejects the inclusion of revisions published by another user is prospectively prevented from publishing revisions to other users, until the user accepts the previously rejected published revisions. The invention employs a distributed architecture that allows each user to interact with that user's working copy of the database in a way that is controlled by that user without impairing the functionality of the database for other users. The database inconsistency allowed by the invention facilitates the performance by users of "what-if" analyses.

ABSTRACT:

The invention concerns a relational data base control system stored in a first storage unit (11) controlled in accordance with a first relational access logic, and including at least a series of records, each of the records being associated with an object including at least one variable and at least one method used to affect the value of at least one of the variables, data retrievals and/or modifications being made solely on the objects in accordance with a second object oriented access logic, the system comprising:

a second temporary object storage unit (15);

a control unit (14) including an automatic command generator unit (113) to be used in the data base according to the first access logic starting from commands corresponding to the second access logic;

a data transfer unit (16) transferring data in each direction between the first storage unit (11) and the second storage unit (15), data transfers between the first and the second storage units (15) being controlled by the automatic command generator unit (113) in order to limit the number of accesses to the first storage unit (11).

ABSTRACT:

The processing of object-oriented queries so as to retrieve data from a relational database management system (RDBMS) is described. An object-oriented query and at least one prefetch path are received from an object-oriented source (such as an application or user). The prefetch path identifies one or more objects which are desired to be constructed. The object-oriented query is translated to a translated object query, where the translated object query is a relational database query capable of retrieving from the RDBMS data to initialize base attributes of top-level objects identified by the object-oriented query. A set of relational queries is generated from the translated object query and the prefetch path. These relational queries, which are capable of retrieving from the RDBMS data needed to construct the objects identified by the prefetch path, are processed by the RDBMS.
